

DPUMasterSwitch

Switches between two signals at a threshold.

1. Inputs:

<i>Master_In</i>	Master input
<i>Slave_In</i>	Slave input
<i>MasterThreshold</i>	Threshold value. If limit is reached, switch from <i>Slave_In</i> to <i>Master_In</i> happens.

2. Outputs:

<i>IsMaster</i>	= 1, if <i>Out</i> = <i>Master_In</i> = 0, if <i>Out</i> = <i>Slave_In</i>
<i>Out</i>	Output of DPU

3. Functional principle:

The output *Out* of the DPU is either switched to the input *Master_In* or to the input *Slave_In*. If the absolute value of *Master_In* is higher than the limit *MasterThreshold*, then the output is switched to *Master_In* and the output *IsMaster* is set to 1. If the value is smaller, then the output is switched to the current value of *Slave_In* and *IsMaster* is set to 0.
