

DPUMonoFlop

Detects changes of the input value and sets the output value for just one simulation step.

1. Inputs:

In Input value

2. Outputs:

Out Output value

3. Functional principle:

DPUMonoFlop investigates if the input value has changed in comparison to the last simulation step.

If the current value of $In > 0$ is *true*, and the value of *In* was = 0 (*false*), then the output is set to *Out* = 1 (*true*).

In all other cases the output value is 0 (*false*).
